"Effect of Petroleum Cracking Products on the Animal Organism,"  
by A. G. Bogdat'yeva senior scientific associate, and D. Ya.  
Vid, scientific associate, Scientific Research Institute of  
Roentgenology, Radiology, and Oncology, Ministry of Health Azer-  
baydzh SSR, Gigiyena i Sanitariya, Vol 22, No 5, May 57, pp  
37-40

Experiments were conducted on rabbits to determine the effect of petroleum cracking products -- gasoline, kerosene, and cracking residues -- on the animal organism. The products were applied cutaneously to the outer surface of the ear in doses of one milliliter to one kilogram of body weight. The experiments established that the cutaneous application of the products produced local changes in the skin as well as modifications in a number of internal organs. Local changes were marked by hyperplastic and inflammatory manifestations. The general effect on the animals was marked by intense emaciation and finally death. Of the internal organs, the liver and the sexual organs were affected severely. No cancerogenic effect was noted. (U)

/ 331. Stepanov, A. Ya., and Bogdan, A. I., The penetration

cone sinks into a barrier into the top part of the water. The cone is in the submerged part of the cone. At the bottom of the cone there is a cavity.

Author gives the author's law of the cone. It is shown that the force exerted by the weight of the cone is direct. Under the formation of the equation for this movement, author likewise takes into account the fact that the wetted surface of the cone will be proportional to the submerged part of the cone.

TITLE:

Determination of permanent deformation by the method of transparent, optically sensitive layers

PERIODICAL:

Zavodskaya laboratoriya, v. 27, no. 6, 1961, 721-724

TEXT: To study the states of stress and deformation on the surface of parts, a method with transparent, optically sensitive films has recently been used; a thin layer of optically sensitive material is applied to the surface of the part during its loading; this thin layer is deformed simultaneously with the surface. Polarized light passes the layer, is reflected from the metal (or other) surface, and passes once more the layer and the analyzer. The phase difference of the rays, due to birefringence,  $\delta = 2t_{\text{layer}} C(c_1 - c_2) \text{layer}$ , where  $C$  is the linear phase difference,  $C = \lambda/\sigma^{(1,0)}$  the optical stress coefficient of the layer material,  $t_{\text{layer}}$  the thickness of the layer,  $\sigma^{(1,0)}$  the optical material

Determination of permanent ...

constant of the layer with respect to stress, and  $\lambda$  is the wavelength of the light used. A level state of stress ( $\sigma_3=0$ ) exists on the surface of the piece and in the layer; therefore,  $(\sigma_1 - \sigma_2)_{\text{layer}} = [(\epsilon_1 - \epsilon_2)_{\text{layer}}] \cdot E_{\text{layer}} / [1 + \nu_{\text{layer}}]$ , where  $E_{\text{layer}}$  is the elastic modulus, and  $\nu_{\text{layer}}$  the Poisson coefficient of the layer. On the premise that the deformation of the layer and that of the piece surface are equal, the following holds:  $(\epsilon_1 - \epsilon_2)_p = (\delta/2t_{\text{layer}}) \cdot [(1 + \nu_{\text{layer}})/C \cdot E_{\text{layer}}] = [\epsilon_0^{(1,0)} (1 - \nu_{\text{layer}})/E_{\text{layer}}] \cdot (m/2t_{\text{layer}})$ , and, after introduction of the optical deformation constant of the material:  $(\epsilon_1 - \epsilon_2)_p = \epsilon_0^{(1,0)} m/2t_{\text{layer}}$ , where  $m$  is the order of the interference band. By this method, it is possible to measure deformation in the elastic, the elastoplastic, and the plastic ranges since the proportionality between the deformations of the layer and the order of the interference band for the majority of optically sensitive materials used for this purpose (including the 3A6-M (ED6-M) material most used in the Soviet Union) at room temperature holds, up to  $t=2$ , until 3%, and at Card 2/5

Determination of permanent ...

\* 100 - 130°C, up to  $\epsilon = 5$ , until 7%. By the same method, it is also possible to measure the permanent deformation under loads beyond the flow limit; here, the layer is applied before loading the part, the part is loaded, and after release the optical phase difference due to permanent deformation is measured. An MN-7 (MP-7) polarization microscope was used for accurately measuring the order of the interference bands in the layer and determining the permanent deformation. As an example, the authors describe the determination of permanent deformation after releasing a flat specimen subjected to pulling stress with a width of the working part of 12.2 mm, a thickness of 2.9 mm, and a central opening of 4.6 mm diameter. The specimen was made of D1AT (D1AT) aluminum alloy ( $E = 7.1 \cdot 10^5 \text{ kg/mm}^2$ ;  $\sigma_s = 19 \text{ kg/mm}^2$ ;  $\sigma_B = 38 \text{ kg/mm}^2$ ). A plate, 1.4 mm thick, made of cold-hardening ЭД6-М (ED6-M) adhesive, is glued onto the specimen before loading. After aligning the edges of the plate with those of the specimen, and drilling the hole, the specimen is loaded with  $P = 610 \text{ kg}$  beyond the flow limit. The nominal mean load in the weakened cross section  $\sigma'_{\text{nom}} = [610 / (12.2 - 4.6) \cdot 2.9] = 27.6 \text{ kg/mm}^2 > \sigma_s$ . Fig. 3 shows a diagram

of the V-shaped reflection polariscope used for taking the interference bands of the whole specimen. The order of the bands in on the circumference of the opening in the specimen and in the interspace between the bands were measured with the compensator of the microscope. The optical deformation constant of the layer material  $\epsilon_{(1,0)}^{(1,0)} = 0.44 \cdot 10^{-3}$  was determined on a calibrated specimen in the form of a band, without an opening, subjected to pulling stress. TITLE: Method of studying elastic-plastic strains under repeated variable loads

SOURCE: Zavodskaya laboratoriya, v. 31, no. 9, 1965, 1116-1119

TOPIC TAGS: stress distribution, plastic deformation, elastic deformation

ABSTRACT: The article describes the application of the method of optically sensitive coatings to the study of elastic-plastic strains under repeated variable loads for local strains of up to 2% and numbers of cycles of the order of  $1 \times 10^3$ . Methods of gluing the optically sensitive layer to the surface of the test piece were studied and various glues were tested in order to produce the required adhesion. A V96 alloy and an optically sensitive layer consisting of EDSM (epoxy resin ED5 with additives) were chosen for the study. It is found that in the range of the highest strains (1.7%), the values of the optical sensitivity of the layer to stresses and strains remain practically constant when the cycles are repeated and the load level is changed. The redistribution of strains and stresses in the zone of an aperture in the center of a plate of V96 alloy was studied under

TITLE: Binding energy and elastic moduli of alkaline metals

SOURCE: IVUZ. Fizika, no. 4, 1965, 134-139

TOPIC TAGS: alkali metal, electron density, nuclear binding energy, crystal lattice parameter, Hartree Fock method

ABSTRACT: The authors present a method of calculating the binding energy in alkaline metals, using a method in which the statistical approximation is regarded as a zeroth approximation of the single-electron approximation, the latter being represented in the form of an expansion in powers of Planck's constant  $\hbar$ . Under such an assumption, the energy of the system can be represented as a certain functional of the density of the electrons comprising the system, so that the binding energy, the lattice constants, and the elastic moduli of the alkaline metals can be calculated by using this functional. The single-electron functions used in the calculations are obtained by the Hartree-Fock self-consistent field method. The results are found to be in good agreement with experiment. Comparison of theory with experiment is given for Na, K, Rb, and Cs. Orig. art. has: 22 formulas and 1 table.

TITLE: Optical constants of fused quartz in the far infrared region

SOURCE: Zhurnal prikladnoy spektroskopii, v. 4, no. 1, 1966, 68-70

TOPIC TAGS: quartz, refractive index, light absorption, IR absorption, IR spectrum

ABSTRACT: The transmission and reflection spectra for specimens of fused quartz of various thicknesses were measured in the 60-560  $\mu$  wavelength range. The resultant data were used for determining the indices of refraction ( $n$ ) and absorption ( $k$ ). The reflectance of a plate 25 mm thick was used for determining the index of refraction in the 50-90  $\mu$  wavelength range. In the 220-400  $\mu$  region the index of refraction was determined from the position of the maxima and minima in the interference transmission spectrum of a plate 0.258 mm thick. The data show a reduction in  $n$  from 2.07 in the 50  $\mu$  region to 1.94 at 90  $\mu$ . In the 220-400  $\mu$  region,  $n$  remains practically constant, varying from 1.89 to 1.92 with an average value of 1.91. The

Card 1/2

UDC: 535.312

index of absorption was calculated from the coefficients of transmission for plates with thicknesses of 1.05, 2.03, 4.07 and 12.35 mm with regard to the values of the refractive index. A curve is given showing the index of absorption as a function of wavelength for fused quartz at room temperature. This curve shows a reduction in  $k$  from 0.0165 at  $60 \mu$  to 0.0038 at  $560 \mu$ . The transmission factor of fused quartz is independent of temperature in the  $250-550 \mu$  region. Orig. art. has: 2 figures, 2 tables.

Bucharest, Studii si Cercetari de Inframicrobiologie, Vol 17,  
No 5, 66, pp 377-387.

Abstract: An anti-measles vaccine prepared with modified live M60-5Huang virus was tested on 220 children. Only minor clinical reactions resulted, with a complete absence of rashes or convulsions. One month after vaccination serum conversion was 79.41 percent, and the titer of anti-measles hemagglutination-inhibiting antibodies varied between 1/80 and 1/320. After 4 months the corresponding values were 75 percent and 1/40 to 1/80. Thus the vaccination seems to confer a specific immunity, which so far has protected the vaccinated children against measles.

TITLE: Hydraulic resistances in the air channel of a heat exchanger as a function of the configuration of the circulating section

SOURCE: Avtomobil'naya promyshlennost', no. 12, 1966, 8-11

TOPIC TAGS: heat exchanger, gas turbine engine, hydraulic resistance, fluid flow, plane flow

ABSTRACT: The authors study hydraulic drag in individual sections of the air channel of the heat exchanger for automotive gas-turbine engines. The experimental method is based on introducing a dye into a plane-parallel fluid flow for visual observation of stream lines. The accompanying figure shows the experimental installation which consists of plate holder I, pump unit, device II for pressure feeding the dye into the flow being studied, panel III with measuring instruments (mercury manometer and nine piezometers), a device for measuring rate of flow by the volumetric method and an attachment for taking photographs. Water is used as the working medium at a temperature of 13-14°C (kinematic viscosity 0.0115 cm<sup>2</sup>/sec). Rate of water flow was varied from 7 to 70 cm<sup>3</sup>/sec. Hydraulic resistance in individual sections of the channel was

Card 1/3

UDC: 621.43:129.113:62-714

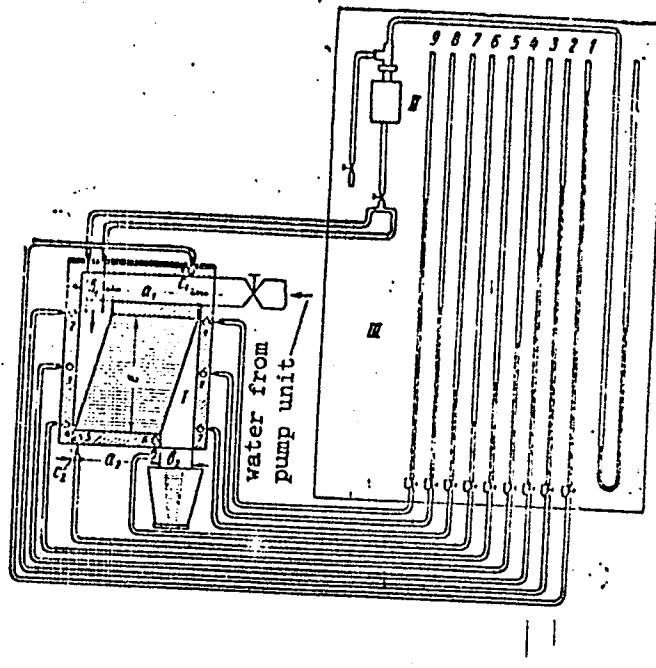

ACC NR: AP7006714

determined from the difference in the readings of the respective piezometers. The ratio of the total head to the average velocity head in the channels of the corrugated plate was taken as the criterion for evaluating hydraulic resistance of the heat exchanger. The velocity field in the circulating section of the heat exchanger was analyzed from photographs of the configuration and relative positions of the stream lines shown by the liquid dye. The proposed method was found to be simple and effective. The lowest hydraulic resistances in the circulating section of the heat exchanger correspond to uniform distribution of the flow with respect to the channels of the corrugated plate. Flow conditions during input from the supply channel to the channels of the corrugated plate differ considerably from conditions during outlet of the fluid into the discharge channel with identical average velocities at inlet and outlet. Losses in the discharge channel are considerably greater than in the supply channel. As the Reynolds number increases, the drag coefficient which is common for the entire heat exchanger decreases. This reduction becomes more pronounced with an increase in the delay of flow turbulence in individual parts of the circulating section. As the velocity field in the discharge channel becomes more uniform, retardation in flow turbulence increases. Turbulence may be delayed to a Reynolds number of 1700 when the flow is well organized (dimensions of supply and discharge channels in mm [see figure]:  $l=120$ ,  $a_1=70$ ,  $b_1=35$ ,  $c_1=10$ ,  $a_2=83$ ,  $b_2=42$ ,  $c_2=1$ ). Flow turbulence in the discharge channel takes place earlier than in the supply channel due to the transverse velocity of the fluid leaving the channels of the corrugated plate. Hydraulic losses

Card 2/3

ACC NR: AP7006714

in the air channel of a heat exchanger may be minimized by equalizing the velocity field. This may be achieved by using a corrugated plate with a trapezoidal shape and by a relative reduction of the average velocities in the supply and discharge channels as compared with the velocities in the channels of the corrugated plate. Orig. art. has: 4 figures, 2 tables, 4 formulas.

AUTHORS:

Bogina, L. L.; Martyukhina, I. P.

TITLE:

On the Photocolorimetric Determination of Cobalt in Rubbers  
Using Nitroso-R-Salt

PERIODICAL:

Kauchuk i Rezina, 1959, No. 11, pp. 58-59.

TEXT: The authors outline the principle of the photocolorimetric method for determining cobalt in rubber using nitroso-R-salt: the nitroso-R-salt forms a complex compound of reddish color, soluble in water, i.e., sodium 1-nitroso-2-naphthol-3,6-disulfonate, reacting with cobalt in a medium close to neutral or weakly alkaline. An acetate medium is the most favorable one for the formation of the complex compound at pH = 7-8. The excess acidity slows up the process of the complex compound formation. The presence of the following metals do not interfere with the cobalt determination: Al, Fe, Mn, Zn, Ca, Mg, Cu, Ni, Pb, Ti, etc. Some of these metals do not react with the nitroso-R-salt at all, such as Al, Zn, Ca, Mg, Pb, Ti, etc. The colorimetric analysis was carried out on a ФК-М (FEK-M) instrument with a green light filter, so that the complex solutions of the cobalt

S/138/59/000/011/010/011  
A051/A029

On the Photocolorimetric Determination of Cobalt in Rubbers Using Nitroso-R-Salt

absorb the light intensively, whereas the solution of the nitroso-R-salt hardly absorbs light at all and the colored solutions of the cobalt complex obey Beer's law. The laboratory procedure for obtaining the date (Table 1) on the optical density average values is outlined. A calibrated curve is plotted according to these data. The cobalt concentration is measured in mg/100ml. The formula for computing the cobalt content is given as: % Co =  $\frac{c \cdot 500 \cdot 100}{g \cdot 1000 \cdot n}$ , where c is the cobalt quantity found according to the

calibrated curve, in mg; g is the rubber portion, in g; 1000 the coefficient of transforming the mg to g; n is the quantity of solution, transferred from the measuring flask with a capacity of 500 ml to a measuring flask with a capacity of 100 ml (10, 15, 25 ml). Table 2 gives the results of the cobalt determination in chemically pure compounds, in mg. If the content of cobalt is over 0.5%, the above formula is changed to: % Co =  $\frac{c \cdot 500 \cdot 100 \cdot 100}{g \cdot 1000 \cdot 25 \cdot n}$ ,

where n is the quantity of solution transferred from solution II into a measuring flask with a 100 ml capacity for colorimetric analysis (10, 15,

On the Photocolorimetric Determination of Cobalt in Rubbers Using Nitroso-R-Salt

25 ml). The margin of error in the cobalt determination fluctuates between - 0.0002 to + 0.0005 for a cobalt content less than 0.1 mg, and between - 0.0006 to + 0.0013 mg for a cobalt content over 0.1 mg. These results are considered satisfactory. Table 3 shows that the results obtained by the photocolorimetric method coincide with the computed values of cobalt content determination in rubber. The photocolorimetric method for determining the cobalt content in rubber using the nitroso-R-salt is highly sensitive, accurate and simple to perform. The duration of one analysis, not considering the ashing of the rubber portion, is 1.5 to 2 hours. The reagents are easily obtainable. There are 3 tables and 5 Soviet references.

TITLE: Controlling the Magnitude of the Stresses in Reinforcement  
Tensioned on Formwork During Casting of Constructions  
(Kontrol' velichiny usiliya v armature pri izgotovlenii  
konstruktsiy s natyazheniyem na upory)

PERIODICAL: Beton i Zhelezobeton, 1958, Nr 8, pp 311 - 313 (USSR)

ABSTRACT: The SN 10-57 gives instructions on design of pre-cast  
pre-stressed reinforced concrete constructions, taking  
into account losses caused by friction during tensioning  
of both bent as well as straight reinforcement. This  
handbook gives magnitude of friction coefficients. Various  
aspects of losses in tensioning of reinforcement are  
investigated and their respective formulae are given.  
Figure 1 shows diagram of stress dispersion along the  
lengths of reinforced element. Due to the effect of  
friction, the characteristic shape of prolongation of  
reinforced element occurs (Figure 2). To define character-  
istic friction, results of three friction measurements are  
taken into account. Further friction calculations are  
taken during each stage and so the mean value of the  
friction is ascertained. The measurements should be
